Chapter One: Philosophy and Theoretical Foundations of the Niyaee Greenhouse City

Part One: An Introduction to the Niyaee Planetary Greenhouse City

In an era where humanity confronts unprecedented challenges in environmental degradation, energy crises, social inequality, and the collapse of urban fabrics, the imperative to reimagine urban paradigms has never been more urgent. Contemporary cities—predominantly conceived during the nineteenth and twentieth centuries upon the foundations of the Industrial Revolution and machine-centric thinking—despite their remarkable technological and economic achievements, have inflicted devastating environmental and social consequences upon the world. Air pollution, paralyzing traffic congestion, the vanishing of green spaces, the reckless consumption of natural resources, the destruction of fertile soils, and humanity's ever-widening estrangement from nature constitute merely a fraction of these ramifications. Amidst this landscape, the concept of the **Niyaee Planetary Greenhouse City** emerges as a pioneering paradigm to address these afflictions—a city wherein architecture, technology, economy, and culture are interwoven, pursuing an elevated aspiration: to restore humanity to the embrace of nature, without

relinquishing the advantages of modern civilization.

The Niyaee Planetary Greenhouse City is grounded upon a philosophy that may be termed "Returning to Nature through Intelligent Means." This city is not merely a residential complex, but rather a complete ecosystem wherein humans, plants, animals, water, soil, and air coexist in sustainable equilibrium. Its design draws upon patterns forged by billions of years of evolutionary experience in nature. The colonies of honeybees, ants, and termites present extraordinary exemplars of collective organization, resource efficiency, and environmental sustainability—patterns from which humanity may draw profound inspiration. These creatures, without depleting resources indiscriminately or devastating their surrounding environment, construct complex and efficient societies. The Niyaee City, emulating these natural systems, endeavors to offer a similar model for human habitation.

The honeybee, one of Earth's most wondrous creatures, presents an unparalleled paradigm of cooperation, division of labor, and self-organization. Within the beehive, there exists no central manager or commander issuing directives to all. Yet millions of bees operate in

perfect harmony. Each bee possesses a specific duty, and without owning the hive or its resources, dedicates its entire existence to serving the colony. Bees nourish themselves from the nectar of flowers, yet simultaneously serve nature through pollination. They produce honey—not only for their own sustenance but also as a reserve for the colony's survival during colder seasons. This cycle of production and consumption occurs without waste or pollution. The Niyaee City is designed upon this very paradigm: a city wherein every citizen serves the whole, and the whole serves every citizen, with all things flowing within a sustainable, waste-free cycle.

Ants present yet another paradigm of collective living. They construct intricate subterranean cities wherein ventilation systems, storage facilities, and larvae nurseries are designed with remarkable intelligence. Ants continue their existence without depleting resources indiscriminately or devastating their surroundings. Even under harsh environmental conditions, they discover astonishing solutions. The Niyaee City, inspired by ants, has designed an underground freight system that fulfills citizens' needs without heavy, polluting vehicles. This system operates

with complete intelligence and self-regulation, functioning optimally without centralized human management.

Termites rank among nature's most remarkable architects. They construct colossal structures of unparalleled engineering sophistication. These edifices feature natural ventilation systems that maintain interior temperature and humidity within optimal ranges. Without consuming electricity or fuel, termites accomplish this through simple yet ingenious applications of physical principles. The Niyaee City, drawing inspiration from this system, has designed an intelligent ventilation network that preserves pleasant air throughout the year without fossil fuel consumption. Through water channels, natural wind towers, and transparent rooftops, this system maintains temperature and humidity within ideal parameters.

The philosophy of non-ownership and public shareholding is one of the fundamental pillars of the Niyaee City. In contemporary cities, the concept of private ownership has become one of the most significant factors contributing to social inequality. Individuals who own more land or property become wealthier, and this effortless wealth is transferred from

one generation to the next. This system encourages hoarding, speculation, and price manipulation, keeping a large portion of society's resources in the hands of a limited few.

In the Niyaee City, this concept has been entirely eliminated. Land, buildings, and all urban facilities are provided to all citizens as public shares. Every citizen is a shareholder of the city and benefits from its resources, but no one is the exclusive owner of anything. This system is rooted in Islamic philosophy, which considers humans as God's vicegerents on Earth, not its owners. Humans are trustees of natural resources and must preserve them for future generations.

This thinking has been combined with blockchain patterns and smart contracts, creating a legal system in which conditional usufruct (right of use) has replaced absolute ownership (full ownership). Citizens can use houses, facilities, and city services, but they have no right to sell or destroy them. This system is controlled by digital smart contracts and requires no courts or enforcement officers. If someone attempts to destroy or sell public property, the system automatically reacts and deprives them of city services. This method guarantees social justice without the need for force or

coercion. The goals and primary missions of the Niyaee City extend far beyond merely providing housing for people. The first and most important goal is soil preservation and the restoration of its capabilities. In contemporary cities, thousands of hectares of fertile land are buried under concrete and asphalt, effectively removed from the production cycle. These lands can no longer support plant growth, and underground water tables are not replenished. The Niyaee City, by adopting an explicit policy of no excavation, strives to preserve soil as a vital asset. Not even a single square centimeter of soil should be destroyed, because soil is the mother of all life, and without it, agriculture, nutrition, and human survival are impossible.

The second goal is preserving the water cycle. In modern cities, concrete and asphalt prevent rainwater from penetrating the ground, and instead of replenishing underground aquifers, this water flows as surface runoff into sewers and is wasted. In the Niyaee City, the entire city surface is covered with permeable materials so that rainwater easily infiltrates the soil and replenishes underground aquifers. This policy, along with water channels designed throughout the city, preserves the natural water cycle and makes the city

self-sufficient in water, independent of external water sources.

The third goal is eliminating polluting vehicles and creating a smoke-free and noise-free city. Private cars are one of the largest sources of air pollution, greenhouse gas emissions, and noise in cities. They also occupy a large portion of the city's surface and reduce quality of life. In the Niyaee City, combustion vehicles have been completely eliminated, and transportation is provided by clean means such as autonomous boats, electric scooters, intelligent monorails, and smart cable cars. These vehicles, without producing pollution or noise, transport citizens to their destinations and transform the city surface into a calm and safe space for pedestrians.

The fourth goal is creating a self-sufficient and energy-sustainable city. The Niyaee City, using solar panels installed on roofs, natural wind towers, and energy recycling systems, has reduced its need for fossil fuels to zero. This city produces excess energy and can export surplus energy to surrounding areas. This approach makes the city independent of external power grids and resilient against energy crises.

The fifth goal is creating a healthy and vibrant environment for citizens. The magnificent greenhouse on the ground floor, abundant parks and green spaces, beautiful water channels, and clean air all contribute to the physical and mental health of citizens. In contemporary cities, many chronic diseases such as asthma, allergies, depression, and anxiety are caused by air pollution, lack of green spaces, and urban stress. The Niyaee City, by eliminating these factors, provides an environment in which citizens can live healthier and happier lives.

The position of the Niyaee City among the cities of the world is entirely unique. This city is neither an ordinary city nor an unattainable dream. It is a practical and implementable model that can serve as a template for future cities. While contemporary cities are heading toward collapse and grappling with environmental, social, and economic crises, the Niyaee City offers a comprehensive solution to all these crises. This city demonstrates that it is possible to build a city where humans and nature coexist without one destroying the other. This city is a hope for future generations to live in a healthy, sustainable, and equitable environment.

The Niyaee City is not merely a construction project

but a cultural and civilizational revolution that can change the course of human history. With such unique features, the Niyaee City can serve as a model for the reconstruction of worn-out cities and the construction of new cities around the world. Many urban planning experts believe that contemporary cities have reached a point of no return, and the only solution is to build new cities based on sustainable principles. The Niyaee City is an answer to this need—a city in which everything is designed from the outset based on scientific and environmental principles. This city demonstrates that urban development and environmental protection are not only not in conflict with each other, but can be complementary.

One of the most significant aspects of the Niyaee City is its adaptability to climate change. As the Earth warms and sea levels rise, many coastal cities face the serious threat of erosion and submersion. The Niyaee City, with its unique design, can withstand these threats. The sealed glass roof prevents rainwater and storms from entering, while intelligent ventilation systems maintain temperature and humidity within the optimal range. This city can even be constructed in areas located below sea level, as its structure is

completely sealed and resilient. This feature makes the Niyaee City an ideal option for countries facing sea-level rise.

Countries such as Bangladesh, the Netherlands, the Maldives, and many oceanic islands are confronting the serious threat of rising sea levels. The Niyaee City, with its greenhouse structure, not only remains safe from this threat but can also serve as a secure refuge for the residents of these regions. This city is a symbol of intelligent adaptation with nature; it neither resists nature nor destroys it, but rather coexists peacefully with it. The Niyaee City is an answer to the climate crisis of the twenty-first century.

Part Two: Dr. Amiri and Dr. Ahmadi's Introduction to the Niyaee Greenhouse City

Dr. Amiri and Dr. Ahmadi stepped out of the airport and boarded an electric bus that was taking them toward the Niyaee Greenhouse City. The air was hot and humid, but the moment they entered the city's boundaries, they felt a noticeable change in temperature and humidity. A massive glass ceiling appeared in the distance, arching over the sky like a grand dome. Dr. Ahmadi, who had spent years researching environmental science, couldn't help but ask: "How can all this glass and metal possibly be environmentally compatible?"

The bus arrived at the main entrance. A grand gate, designed with inspiration from bee wings, opened gently. As they entered the city, the first thing that caught their attention was the complete absence of any asphalt or concrete roads. Instead, they saw paths made of natural soil and grass, among which various bushes and plants had been planted. Dr. Amiri, an agricultural expert, said in amazement: "This soil is completely alive. Look how it retains moisture? This means the groundwater tables are being replenished, unlike modern cities where asphalt prevents water infiltration."

They got off and headed toward the first residential complex. A ten-story building with glass and green facades stood before them. The ground floor entrance was a large greenhouse, covered from floor to ceiling with various plants. The sound of water flowing from a canal along the greenhouse wall could be heard. Dr. Ahmadi said in awe: "This means the ground floor is a complete ecosystem. Plants, water, ventilation, all working together."

Dr. Amiri smiled and said: "I think this city is a living laboratory. Do you know why the air is so pleasant? Because plants regulate humidity through transpiration and reduce temperature. This is the same mechanism that occurs in nature, but has been destroyed in modern cities by concrete and asphalt."

They entered the greenhouse. The interior air was neither cold nor hot, but perfectly balanced. Sunlight filtered through the glass ceiling onto the green, vibrant leaves. Fruit-bearing bushes such as pineapple, raspberry, and strawberry had been planted in the spacious area, with their ripe fruits displaying magnificently. Various vegetables and summer crops like cucumber, tomato, pepper, squash, and eggplant were growing in hydroponic cultivation beds. Dr.

Amiri walked toward one of the beds with interest and examined its soil. He said: "This soil is completely organic. No chemical fertilizers have been used. This means the products are completely healthy and natural."

Suddenly, a gentle whistle was heard from a distance. A small white boat passed over the water canal flowing alongside the greenhouse. A passenger sat inside the boat, absorbed in reading. Dr. Ahmadi said: "Driverless boats! This means vertical and horizontal transportation are all intelligent. Can you see that there are no gasoline or diesel vehicles? This city has no air pollution."

They exited the greenhouse and entered the first floor. This floor had a height of approximately five meters and was filled with service and educational spaces. A large library with natural light, modern-equipped classrooms, medical clinics, and cultural spaces were visible. Dr. Ahmadi said: "The five-meter height of this floor not only improves ventilation but also gives a sense of openness and freedom. In modern cities, low ceilings create a suffocating feeling."

Dr. Amiri confirmed: "And most importantly,

everything is within a five-minute distance. School, clinic, store, all are on this floor or the second floor. There's no need to spend hours in traffic to reach a service center."

They boarded the escalators and went to the second floor. This floor also had a five-meter height and was designed for light industrial production. Small workshops were visible where electronic and industrial components were being produced using 3D printers and CNC machines. Dr. Ahmadi said with admiration: "This means production happens exactly at the point of consumption. There's no need for large, polluting factories outside the city. Everything is produced in the heart of the city, with minimal energy and material consumption."

They walked toward the staircase to go to the residential floors. On the way, they encountered some residents. Everyone looked happy and cheerful. A middle-aged woman said with a smile: "Welcome. If you have any questions, I'd be happy to help you." Dr. Amiri asked: "How is this place managed?" The woman replied: "Everything is run by artificial intelligence and collective decision-making. We have meetings every week and decide on city matters. No

one is an owner; we are all shareholders."

They reached the third floor. This was the first residential floor, with a height of two meters and eighty centimeters. The apartment doors were open, and one could see inside. Each apartment had a balcony that opened onto the greenhouse of the ground floor. Dr. Ahmadi said: "This means every family has a personal garden. In modern cities, our apartments are like concrete cages, but here, nature is part of the home."

Suddenly, the announcement system's voice echoed: "Attention: Monorail number seven has capacity for new passengers. Please proceed to the station." Dr. Amiri said: "Small, self-driving monorails. This means public transportation without congestion and without delay. If one breaks down, another replaces it. This is similar to computer systems that have redundancy."

They boarded the monorail and headed toward the city center. Through the window, they watched the city. One hundred residential complexes, like one hundred concentric rings, were positioned next to each other. The distance between each complex was about one hundred meters, filled with green spaces and service areas. Dr. Ahmadi said: "This city is a living colony.

Like a beehive, every section has its own task, but everyone works together. No section is separate from the rest."

The monorail took them to one of the aerial bridges connecting two complexes. From there, the entire city could be seen. The glass ceiling showed the blue sky, and sunlight gently shone on the plants and buildings. Dr. Amiri said with longing: "In modern cities, we waste our entire lives in traffic and pollution. Here, time is spent on real living, not commuting."

Suddenly, the sound of birds was broadcast from hidden speakers. Dr. Ahmadi said: "Birdsong! This means they live in this city. How is that possible?" Dr. Amiri explained: "The glass ceiling has openings for birds to enter. They can come through these openings and live in the green spaces between complexes. This city is designed not only for humans, but for all living creatures."

They got off and walked toward one of the public gardens. Children were playing, young people were running, and elderly were sitting on benches chatting. There was no car horn, no smoke, no annoying noise. Only the sound of water, birds, and children's laughter.

Dr. Ahmadi, pointing to their surroundings, said: "This is exactly what we used to talk about in theory regarding sustainable cities. But here, it's reality."

Dr. Amiri thoughtfully said: "Do you know why this city is so active and dynamic? Because it has learned from nature. Bees, ants, and termites have been living for millions of years without ownership, without pollution, and without crisis. We humans thought we had to rule over nature, when in fact we should be learning from it."

They sat on a bench and gazed at the various corners of the city. The sun was setting, and golden light shone on the glass ceiling. Dr. Ahmadi said: "This city was a dream that has now become reality. But the question is: Are we humans ready to live in such a city? Can we let go of ownership and live together, like bees, for each other?"

Dr. Amiri confidently replied: "This city is not an ending, but a beginning. A city that reconciles humans and nature. A city that proves living without destruction is possible. It may take a hundred years for all cities in the world to become like this, but this city has shown that a bright future exists."

They stood up and walked toward their accommodation. On the way, Dr. Ahmadi said: "Do you know what impressed me the most?"

Dr. Amiri asked: "What?"

He replied: "That this city is a living organism. It breathes, it grows, it repairs itself. This is not architecture; this is biology."

Dr. Amiri smiled and said: "Perhaps that's why it's called the Niyaee City. Niyaee means returning to roots. Returning to the time when humans were part of nature, not its master."

Chapter Two: Architecture and Infrastructure of the Niyaee Greenhouse City

Part One: Technical Structure and City Design

The Niyaee Planetary Greenhouse City is designed with a capacity of one million residents organized within one hundred residential complexes, each hosting ten thousand citizens. This population structure has been established based on precise social, economic, and environmental calculations. The selection of one million as the city's population represents the outcome of extensive analyses demonstrating that this number serves as the optimal minimum for creating a self-sufficient city with sufficient occupational, cultural, and social diversity, while simultaneously functioning as the maximum population that can be managed without excessive expansion and environmental degradation. Each residential complex is designed as an independent unit equipped with all essential facilities, ensuring that residents do not need to leave the complex's boundaries to meet their daily needs. This approach realizes the concept of "a city within a city."

The design of this city is based on a ten-story structure with no basement or underground floors, representing one of the fundamental innovations in Niyaee architecture. Multiple reasons exist for eliminating

underground levels, with the most significant being the protection of soil and the prevention of any drilling or excavation in the ground. This city is constructed in coastal areas that are at sea level or below sea level, and in such regions, underground excavation is not only difficult and costly but can also damage underground water tables and the ecological balance of the area. Consequently, the architects of Niyaee decided to provide all required spaces within above-ground floors, resulting in a structure where the ground floor, first floor, and second floor are designed with a height of five meters, while the remaining seven floors each have a height of two meters and eighty centimeters. The generous height of the first and second floors provides optimal ventilation and lighting conditions for service, educational, healthcare, cultural, and recreational spaces, with these floors hosting all social and economic activities of the residents.

The greenhouse on the ground floor serves as the beating heart of the Niyaee city, playing a key role in air ventilation, environmental beautification, and maintaining the city's moisture balance, in addition to supplying part of the residents' food needs. This greenhouse is equipped with a glass ceiling and

intelligent ventilation system, where summer crops required by the residents are cultivated. This approach minimizes the distance between the farm and the residents' tables while providing fresh and organic products to the inhabitants. The presence of this greenhouse on the ground floor and the one-hundred-meter spaces between complexes has created an image of nature flowing within the heart of the city. Citizens can enjoy the beauty of plants, the sound of birds, and the flow of water at any moment, eliminating the need for travel to distant natural areas and freeing citizens' time and energy for more productive activities. Furthermore, the greenhouse functions as a natural lung, absorbing carbon dioxide and producing oxygen while significantly contributing to improving the city's air quality.

The water channels flowing through the ground floor represent one of the key elements of Niyaee's design, simultaneously serving multiple vital functions. These channels are primarily designed for environmental beautification and creating attractive landscapes for tourists, while also forming the city's maritime transportation system. Self-driving boats moving on rails installed at the channel floor handle the

transportation of goods and citizens, serving as a complete replacement for the heavy and polluting vehicles of modern cities. The boats do not move based on water current but rather traverse on rails installed within the channel, a feature that enables precise control over speed and direction. Utilizing water channels for transportation offers numerous advantages, including a significant reduction in air and noise pollution, a decrease in road accidents, and the elimination of asphalt roads whose impermeability prevents the replenishment of underground water tables.

The smart monorails, designed in small dimensions and in large quantities, constitute the main transportation system of the city for passenger transit, and this system is designed based on the principles of ocean liner ships in which all components operate in an integrated and coordinated manner. The small dimensions of the monorails have been chosen so that if one unit malfunctions, the next unit immediately replaces it, and the transportation system continues without any interruption. This approach is inspired by distributed systems in nature, in which no single part is critical, and the failure of one component does not paralyze the

entire system. The monorails are fully autonomous and are controlled by artificial intelligence, allowing passengers to reach their destinations without the need for a driver or frequent stops.

The ventilation and isolation system of the Niyaee City is one of the most complex yet efficient engineering systems employed in this city. The city is designed to be isolated from all directions, and no snow, rain, or external wind penetrates the city, and this feature provides the ability to fully control the climatic conditions inside the city. The city's roof is made of transparent and resistant material that directs sunlight into the city to the necessary and desirable extent, while also providing sufficient resistance against strong winds, heavy rainfall, and even earthquakes. The smart ventilation system maintains the temperature and humidity of the air at an ideal level throughout all seasons of the year, and using artificial intelligence algorithms, adjusts the conditions based on the number of citizens present, economic activities, and the external weather conditions. This system circulates pleasant and comfortable air throughout the city and minimizes temperature differences between different points of the city.

The construction of the Niyaee City is carried out using prefabricated components, and this approach dramatically increases the construction speed and eliminates the need to transport millions of tons of construction materials. In traditional methods of city construction, thousands of trucks carrying concrete, iron, sand, and gravel must be transferred to the construction site, which brings heavy traffic, air and noise pollution, and road destruction. However, in the Niyaee City, all components are produced and initially assembled in factories and then transferred to the installation site, and this method reduces construction time from years to months. Prefabricated components are mounted on piles that are bolted to the ground, and there is no need for deep concrete foundations, and this ensures the protection of the soil and prevents damage to the earth's structure.

One of the fundamental principles of the Niyaee City is absolute protection of the soil, and for this reason, no excavation is carried out in the ground. This decision is rooted in a philosophy that views soil as a living and valuable entity on which the life and survival of future generations depends. In modern cities today, thousands of buildings sink deep into the ground with deep

concrete foundations, groundwater aquifers are destroyed, and the natural structure of the soil is permanently altered. However, in the Niyaee City, buildings sit on the surface of the earth, and only lightweight metal piles are used as supports, which are installed without damaging the soil structure. This approach ensures that the soil can continue its life, the natural water cycle in groundwater aquifers is preserved, and even restored and strengthened.

The one-hundred-meter distance between each complex and the next provides an exceptional opportunity for delivering diverse and advanced services to residents, and this distance has been precisely designed based on the "five-minute access" principle. Within this space, all essential services—including educational, medical, cultural, sports, commercial, and utility facilities—are situated, enabling citizens to reach all these amenities on foot in less than five minutes. This design eliminates the need for vehicles for daily commutes, freeing up citizens' time and energy for productive activities. Furthermore, the distance between complexes has been designed to create sufficient space for beautiful landscapes for residents.

In the design of the Niyaee Planetary Greenhouse City, one of the most intelligent and inspiring innovations is the allocation of a dedicated one-hundred-meter space between residential complexes. This distance, which may superficially appear to be merely an unused area, actually serves as the beating heart of social interactions, psychological well-being, and tourism attraction in this city. When viewed from above, this city resembles a vast space laid out in a regular and geometric pattern among one hundred residential complexes, with beautiful green strips of shrubs, flowers, and various plants spread between them—not only doubling the city's visual beauty but also fulfilling numerous vital functions.

In this interstitial space, in addition to the various services that citizens can use for exercise, recreation, and other purposes, a range of service facilities has also been planned. Small, beautiful hotels nestled among these gardens serve as accommodations for tourists who wish to live in this city for a while and become closely acquainted with the residents' lifestyle. Small, well-equipped medical centers are also situated in these spaces so that citizens can quickly access healthcare services when needed. Additionally, small

entertainment and cultural centers have been designed in these spaces, including libraries, small performance halls, and play areas for children. These centers not only meet the daily needs of residents but also serve as meeting points and social interaction hubs, strengthening the sense of belonging to the neighborhood among citizens.

One of the most attractive and unique features of the interstitial green space is the allocation of a section for housing various beautiful and harmless birds and animals. In these interstitial gardens, colorful birds of different species—such as parrots, African greys, finches, canaries, and various ornamental birds—live, whose pleasant sounds enrich the city's atmosphere with natural and soothing music. In addition to birds, small, adorable animals such as white and gray rabbits, agile squirrels, soft-fleeced lambs, and beautiful gazelles are also kept in these spaces. Small deer, with their exquisite movements, add a special beauty to these gardens. These animals are not only appreciated as beautiful living creatures but also play an important role in educating children and strengthening the sense of responsibility and affection toward living beings among city residents.

In specific sections of this green space, occasional displays of wild animals have also been arranged. These displays, which are conducted with full compliance with animal welfare principles and without any harm to the animals, provide a unique opportunity for citizens, especially children, to become closely acquainted with wild animals and develop a deeper understanding of wildlife diversity. This experience profoundly impacts children's spirits and introduces them to the values of environmental conservation and respect for animal rights. Furthermore, these displays create extraordinary tourist attraction for the city, drawing many tourists from around the world to this city.

If we step out of the beautiful green inner rings of the city and look at the square-shaped periphery of the city, we encounter another breathtaking landscape. Beyond the residential and greenhouse area of the city, vast agricultural lands and extensive orchards are situated, which are responsible for supplying all the food needs of the city's residents. This section of the city has been intelligently designed to provide food security while causing the least possible damage to the environment, and at the same time, to function as the lungs of the city.

In these peripheral lands, various agricultural products including vegetables, summer crops, fruits, and grains are cultivated. Fruit orchards with diverse fruit-bearing trees, in addition to producing fresh and healthy products, also create a stunning landscape visible from within the city.

Livestock farming and poultry breeding have also found their place in this section of the city. Industrial yet clean and odorless dairy farms, healthy and hygienic poultry farms, and the breeding of goats and sheep provide the protein resources needed by the residents. Aquaculture and fish farming also constitute an important part of this food cycle. Fish breeding ponds are situated alongside farms and orchards, and recycled water from the city is used to feed the fish. This approach creates a completely closed and sustainable cycle in which nothing is wasted and all nutrients return to the cycle. Animal manure is used to enrich the soil of the farms, and contaminated water, after treatment, is used for irrigation.

But perhaps the most important role of this peripheral green space is its impact on air ventilation and environmental purification for the entire city. The extensive orchards and farms surrounding the city

function like a natural filter that purifies the incoming air. Trees and plants absorb carbon dioxide and produce oxygen. Suspended particles and dust are captured by leaves, and clean, fresh air enters the city. This natural ventilation system minimizes the need for mechanical ventilation systems and creates significant energy savings. Furthermore, this green space acts as a natural buffer against strong winds and storms, protecting the city from weather damage.

In fact, the Niyaee Planetary Greenhouse City is a complete and self-sufficient ecosystem in which humans and nature live alongside each other and benefit from one another. The citizens of this city not only meet their daily needs but also live in an environment that contributes to their physical and mental health. The sound of birds, viewing beautiful animals, breathing clean air, and watching lush green farms all provide the residents of this city with an experience that cannot be found in any other modern city. This city proves that it is possible to build a modern and comfortable city by adhering to principles of sustainability and respect for nature, which not only does not harm nature but also helps improve it.

One of the unique features of the Niyaee Planetary

Greenhouse City that distinguishes it from other cities in the world is the attraction of a high volume of tourists and professionals who travel from around the world to visit this innovative city and learn about advanced models of urban planning and architecture. This city is recognized not only as a successful urban model but also as an international scientific and cultural center that hosts thousands of researchers, architects, engineers, urban planners, and enthusiasts in environmental and sustainable development topics from different countries of the world every year. These scientific and cultural interactions not only help transfer knowledge and experiences but also create countless opportunities for international collaborations and the development of new technologies.

Given this high volume of incoming tourists and foreign professionals, there is an urgent need to establish more hotels and accommodation centers around the city, particularly in the square-shaped peripheral section. These hotels must be designed and constructed in harmony with the spirit and architecture of the greenhouse city, while providing appropriate welfare facilities and services for travelers. The design of these hotels is based on green and sustainable

architecture principles, so that their energy consumption is minimized and natural resources are utilized in the most efficient way. The beautiful green gardens surrounding the hotels provide a peaceful environment for travelers to rest, and they can become acquainted with the culture and lifestyle of the city's residents while enjoying natural landscapes.

In addition to hotels, numerous service and commercial centers have also been planned in this section of the city, including traditional and international restaurants, local handicraft shops, cultural and artistic centers, and exhibition spaces for showcasing the city's scientific and technological achievements. These centers, in addition to providing services to tourists, serve as cultural and scientific connection points between the city's residents and the outside world, facilitating the exchange of thoughts and ideas. Many innovative ideas that have been implemented in the Niyaee Greenhouse City are the result of these interactions and dialogues between local and foreign thinkers.

One of the essential and human needs that has received special attention in the design of the Niyaee Greenhouse City is the allocation of appropriate space for cemeteries and burial of the deceased. Death is an

inevitable reality of life, and every city must provide a suitable space for farewell with the departed and paying respects to them. In the Niyaee City, the cemetery is located in the square-shaped peripheral section, amidst orchards and green spaces, to provide a calm and verdant environment for families and survivors.

Overall, the Niyaee Planetary Greenhouse City is an intelligent combination of advanced technology and natural principles, in which all elements of the city, from buildings to transportation and ventilation systems, operate in complete harmony with one another. This city serves as a model for the future of human civilization, in which humans, nature, and technology coexist, and none dominates the other.

Part Two: A Journey into the Depths of Green Architecture

Dr. Amiri entered the magnificent greenhouse of the ground floor with slow, wonder-filled steps. The warm, humid air that touched his face reminded him of spring mornings in his hometown, but with one significant difference: everything here was under precise intelligent control. Sunlight filtered through the strong glass ceiling above, illuminating the space with appropriate intensity and making it pleasant and inviting. The plants planted on both sides of the main pathway, with an astonishing variety of vegetables and greens, painted a vivid, lush image of a modern farm. Cherry tomatoes, red and glistening; eggplants and zucchini; crisp green cucumbers; colorful peppers in shades of yellow and red; various aromatic herbs; and fresh green lettuce leaves all stood together, spreading a delightful fragrance through the air.

Dr. Ahmadi, walking behind Dr. Amiri, said with a voice full of admiration: "Amiri, look how different this is from what we see in modern cities. This greenhouse is not just a food source, but a complete ecosystem that supplies the city's breath." Dr. Amiri, pointing to one of the plants, replied: "Ahmadi, this is

exactly what I have been researching for years. In modern agriculture, we poison the soil with chemical fertilizers, waste water, and destroy the environment. But here, everything exists in a closed, sustainable cycle. Look, these plants are fed by water supplied from underground channels and returned to the soil. Nothing is wasted."

They walked toward the water channel flowing through the center of the greenhouse. Clear, pristine water that, with its gentle movement, instilled a sense of calm and freshness into the space. Wooden benches stood beside the channel, and citizens who were resting or reading enjoyed the beautiful view of plants and water. Dr. Amiri asked in amazement: "Is this water channel just for beauty, or does it have another function?" Dr. Ahmadi, who had already gathered information about the city's transportation system, said with a smile: "No, this channel is one of the engineering masterpieces of this city. Look, those small boats moving on rails installed at the bottom of the channel."

Dr. Amiri looked toward the channel and saw small, white boats moving on metal rails inside the water, completely autonomously, without a driver. Each boat had the capacity for several people and moved at an

appropriate speed. The rail paths were designed to pass through all points of the greenhouse, allowing citizens to access different parts of the city without needing to leave the greenhouse. Dr. Ahmadi explained: "This rail transportation system inside the water is one of the unique innovations of this city. The boats consume very little energy because water and rail friction have been minimized. They move with electrical power supplied by solar panels on the ceiling and produce no pollution."

Dr. Amiri said in awe: "This means that the transportation of goods and passengers in this city is completely clean and emission-free. In modern cities, millions of gasoline and diesel vehicles inject thousands of tons of carbon dioxide and particulate matter into the air daily. But here, there isn't even a single combustion vehicle." Dr. Ahmadi confirmed: "Exactly. And this is only part of the advantages. The existence of these water channels in the greenhouse maintains air humidity at the desired level and, during hot seasons, acts as a natural cooling system. Water evaporation from the channel surface absorbs excess heat and reduces the ambient temperature. This is a passive ventilation system that keeps the air cool and

pleasant without consuming electrical energy."

They passed by the channel and entered another section of the greenhouse where fruit bushes had been planted. Strawberries, pineapples, raspberries, blueberries, and barberries with ripe, glistening fruits painted a dreamlike image of a modern garden. Dr. Amiri, being an agriculture expert, carefully examined the drip irrigation system installed at the base of each bush. Sensors embedded in the soil measured moisture levels and supplied water precisely according to the plant's needs. Not a single drop was wasted, and no plant remained thirsty. Dr. Amiri said proudly: "This precise irrigation system is exactly what I have been promoting for years. In traditional agriculture, we waste thousands of liters of water to irrigate one hectare of land. But here, using artificial intelligence and IoT sensors, water consumption has been minimized. This city can serve as a model for all dry and semi-arid countries in the world."

Suddenly, a soft and gentle voice echoed from the hidden speakers throughout the greenhouse, announcing a change in the internal temperature. Dr. Ahmadi explained: "This is the intelligent ventilation system. Multiple sensors are installed throughout the

greenhouse and the entire city, continuously measuring temperature, humidity, air quality, and carbon dioxide concentration. Based on this data, the artificial intelligence automatically adjusts the ventilation, cooling, and heating systems. On hot summer days, the glass ceiling uses movable curtains to block a portion of sunlight while still allowing sufficient light for plant photosynthesis. At night, the curtains open to release the heat stored during the day into the outside space, reducing the temperature."

Dr. Amiri asked in amazement: "So this system maintains the ideal temperature at all times without human intervention?"

Dr. Ahmadi replied: "Yes, and not just temperature. Humidity, air quality, light levels, and even the concentration of various gases are all under control. If carbon dioxide concentration increases in one section, the ventilation system activates immediately and replaces the air with fresh air. If humidity drops, the water channels and misting system activate. This city is a living organism that constantly regulates itself."

They exited the greenhouse and entered the ground floor, which served as the main passage for boats and

citizens. The high five-meter ceiling evoked a sense of openness and freedom. The glass walls separating the greenhouse from the pathway allowed natural light to penetrate into the ground floor as well. Here, citizens in colorful clothes and smiling faces were going about their business. Some were boarding small boats while others walked. No one was in a hurry; everyone moved with calmness and serenity.

Dr. Amiri said: "Ahmadi, look how different this city is from modern cities. In modern cities, everyone is rushing, everyone is stressed, everyone is stuck in traffic. But here, time has a different meaning. People have time, they have peace, they can talk to each other, they can enjoy nature."

Suddenly, a soft sound was heard from a distance. Dr. Ahmadi pointed toward the ceiling and said: "Look, those are the monorails."

Dr. Amiri glanced up and saw a row of small white monorails moving along tracks installed at the height of the second floor. Each monorail was the size of a small bus and had a capacity for several passengers. Their movement was smooth and vibration-free, producing very little noise.

Dr. Ahmadi explained: "These autonomous monorails are one of the most important transportation tools in this city. They move without a driver and are controlled by artificial intelligence. Their routes are pre-planned, and if one breaks down, another immediately replaces it. Repairs are also done quickly because spare parts are stored at various stations."

Dr. Amiri said with admiration: "This means there will never be traffic. In modern cities, a small accident can paralyze an entire city. But here, the system is designed so that the malfunction of one unit does not disrupt the whole system. This is what we call Fault Tolerance in systems engineering."

Dr. Ahmadi confirmed: "Exactly. And it's not just about the monorails. The entire city is designed based on this principle. If one section fails, the other sections continue working. This city is like an ocean liner; if one compartment floods, the ship doesn't sink because the other compartments are sealed and the ship stays afloat."

They walked in silence for a while, enjoying the greenhouse scenery around them. The gentle sound of water in the canal, the songs of birds nesting in the

green spaces between the complexes, and the soft breeze from the ventilation system all combined to create a soothing atmosphere that could not be found in any modern city.

Dr. Amiri suddenly said: "Ahmadi, do you know why they built this city? To show that humans can live with nature, not against it. In modern cities, we destroyed nature to build cities. But here, we built the city within nature. The pleasant greenhouse space, water canals, fruit bushes, vegetables, colorful flowers, all are part of the city. The city and nature are not two separate things; they are one."

Dr. Ahmadi smiled and said: "Amiri, you're absolutely right. This city is a new paradigm. A paradigm in which development does not mean destruction, but rather coexistence. We can house millions of people in this city without cutting even a single bush, without destroying even a single square meter of soil. This city is the future. A future in which humans and nature have made peace."

They walked toward the greenhouse exit, but before leaving, they looked back one more time. Sunlight streamed through the glass ceiling, creating beautiful

patterns of light and shadow on the green plants, colorful fruits, and the sparkling water of the canal. Citizens walking or resting near the greenhouse had satisfied smiles on their faces.

Dr. Amiri said softly: "Ahmadi, I think this city is not just a city, but a school. A school that teaches us how to live. How to live with nature. How to live together. How to improve our lives without harming future generations."

Dr. Ahmadi placed his hand on his friend's shoulder and said: "Dear Amiri, there are many more wonders ahead. We must see the rest of the city."

Chapter Three: Management, Economy, and Living in the Niyaee Planetary Greenhouse City

Part One: Intelligent Management System and Non-Ownership Economy

In the Niyaee Planetary Greenhouse City, urban management is built on entirely different foundations, the most important of which is the adoption of the integrated management model of ocean liner ships. These massive vessels that transport thousands of passengers across the oceans are an unparalleled example of coordination, self-sufficiency, and crisis management; a system in which no component operates independently and all parts are interconnected in an integrated manner. On an ocean liner, if the main engine fails, backup systems immediately kick in; if a section catches fire, intelligent fire suppression systems activate; and if a passenger experiences a health crisis, the medical team arrives at the location within a fraction of a second. This level of coordination and response speed is the result of years of experience and optimization in the maritime industry, and the Niyaee City has fully embraced this model and implemented it in its structure.

The fundamental difference between the Niyaee City and modern cities today lies in the fact that in current cities, management is administered in a centralized and

hierarchical manner; municipalities, councils, various departments, and diverse organizations, each responsible for a portion of affairs, often facing overlapping responsibilities, slow decision-making, and lack of coordination. However, in the Niyaee City, management operates based on an integrated and distributed system in which artificial intelligence plays the role of the main coordinator. This system functions like the nervous system of a living organism; a central brain that receives information from all points and issues necessary commands, while at the same time, each section of the city operates as an independent cell and can make autonomous decisions when needed. This structure, called distributed or decentralized architecture, makes the city resilient against point failures; if one part of the system encounters a problem, the entire city does not collapse, but other parts come to its aid.

Artificial intelligence in the Niyaee City operates far beyond a supporting tool; this intelligent system is the thinking brain of the city that optimizes all processes. The advanced algorithms employed in this city utilize weighted graph theory to calculate the best transportation routes; in this way, each walking path or

transit route is calculated not only based on physical distance but also on dynamic variables such as shade levels, population density, air quality, and even the energy level of the citizen. This means that artificial intelligence always suggests the route that brings the greatest well-being to the user, not merely the shortest route. If a citizen is tired or has high blood pressure, the system eliminates routes with steep inclines and suggests smoother paths with scenic views. If air quality in a section of the city is low, the system automatically diverts the route toward areas with cleaner air. This level of personalization is only possible through artificial intelligence and massive data processing.

Beyond managing transportation, artificial intelligence also plays a key role in optimizing energy consumption, water management, food distribution, air ventilation control, and even crime prevention and security monitoring. Intelligent systems monitor thousands of variables every moment and make optimal decisions based on them. These decisions include adjusting indoor building temperatures based on the number of people present in each section, turning lights on and off based on available natural

light, distributing water based on the needs of each complex, and even scheduling industrial activities to reduce electricity consumption during peak hours. In fact, the Niyaee City is a living digital organism that, with intelligence and flexibility, predicts and meets the needs of its residents.

One of the most revolutionary aspects of the Niyaee City is the complete elimination of the concept of personal ownership and its replacement with a public shareholding economic system. In this city, land, buildings, and all facilities are provided to residents as public shares, and no individual is the exclusive owner of any part of the city. This approach is rooted in Islamic philosophy, which considers humans as trustees (Khalifa) and custodians of the earth, not as absolute owners. In practice, this means that a citizen cannot sell or destroy public property such as a house, because the property has only been entrusted to them. Blockchain smart contracts guarantee the enforcement of this custodianship condition without the need for courts or enforcement officers. If someone attempts to remove a wall without permission or make unauthorized changes to their unit, intelligent sensors detect this change and the smart contract immediately

reacts; this reaction may include automatic fines, restricted access to services, or even referral to a dispute resolution board.

This economic system completely solves the problem of speculation and hoarding of housing, which has plagued modern cities. In contemporary cities, houses have become investment commodities; wealthy individuals purchase multiple homes and keep them vacant to profit from price increases. This behavior causes housing prices to soar and leaves a portion of the population homeless. However, in the Niyaee City, by eliminating the possibility of free buying and selling, housing returns to its original function of habitation. If a unit remains vacant without an active resident for longer than a specified period, the smart contract invalidates the individual's usufruct rights and returns the unit to the waiting list of citizens in need. This mechanism guarantees the right to housing for everyone and transforms the house from a tool for wealth accumulation into a tool for collective welfare.

In addition to eliminating speculation, the economic system of the Niyaee City utilizes the mechanism of "cost of holding money" or Demurrage, inspired by the theories of the Austrian-German economist Silvio

Gesell. Unlike fiat currency, where accumulation is beneficial, in this system stagnant money loses its value over time. This economic policy eliminates the motivation for speculation and wealth accumulation, forcing capital owners to circulate money in production, innovation, and social services. If a monetary unit is not exchanged in a real economic transaction during a fiscal month, a small portion of its value is automatically deducted and deposited into the city's public treasury. This mechanism transforms money from a stored state to a circulating state and ensures sustainable economic prosperity.

One of the logistical masterpieces of the Niyaee City is the complete elimination of the concept of warehouses. In modern cities, warehouses function as space consumers; large food warehouses where a significant portion of their products spoil while waiting for consumers, or industrial goods warehouses that gather dust for months without being used. However, in the Niyaee City, using an underground logistics system based on swarm intelligence, goods arrive exactly at the moment they are needed. This system utilizes algorithms similar to ant behavior; all cargo capsules are connected to a central intelligent brain, and if one

capsule needs repair or its path is blocked, the system immediately and coordinately changes the routes of all other capsules so that the flow of materials does not stop. This system reduces delivery delays to zero and eliminates the concept of warehouses. Goods are transported underground at high speed without the need for drivers and arrive exactly at the moment of need through vertical chutes directly to the citizen.

This logistics-oriented approach has broad economic implications. In the traditional economy, capital lies dormant in the form of stored goods, imposing costs such as warehouse rent, manpower, insurance, and depreciation on the producer. In the Niyaee City, these costs are eliminated. The producer places the goods directly on the city's logistics line, and the product reaches the consumer immediately. This reduction in overhead costs significantly lowers the prices of goods for citizens. Furthermore, producers, confident in the distribution system, produce only according to instantaneous demand and no longer worry about surplus production and inventory accumulation. This transforms the blind mass production model into an on-demand production model, which is far more sustainable and environmentally friendly.

With its unique design, the Niyaee City possesses extraordinary tourist attractions that can generate substantial revenue for the city. The magnificent greenhouse on the ground floor, with its beautiful water canals, birds and animals appropriate to the space, the sound of water and pleasant breeze, creates a dreamlike image of nature within the heart of the city that cannot be found in any other modern city. Tourists can experience nature in the heart of the city without the need to travel to distant areas. The city's transparent roof, which allows sunlight to pass through as needed, along with intelligent ventilation, creates a pleasant environment in all seasons. Moreover, the unique architecture of the ten-story complexes, the car-free transportation system, self-driving monorails, and rail boats in water canals are all attractions that draw tourists from around the world to this city. Tourism revenue can cover a significant portion of the city's budget and make it financially self-sufficient.

From an environmental and sustainability perspective, the Niyaee City is an unparalleled model. In this city, no asphalt or concrete is used for the city's bed and passages. This decision has been made not only for aesthetic reasons but also for critical ecological

reasons. Asphalt and concrete are impermeable surfaces that prevent water from infiltrating into the soil and groundwater aquifers. In modern cities, rainwater, instead of replenishing groundwater, flows over the city's surface and enters the sewage system. However, in the Niyaee City, with the use of permeable soil, every drop of rainwater can reach the groundwater aquifers and preserve the natural water cycle. This is particularly important in coastal areas where the city is intended to be built. Furthermore, the removal of asphalt eliminates the urban heat island effect—a phenomenon that raises air temperature in concrete cities by up to five degrees above the surrounding environment.

Part Two: End of the Journey and the Dream of the Future

Dr. Amiri and Dr. Ahmadi were sitting on a bench located in a corner of the green rooftop of Complex Twenty-Three. From there, they could see the entire Niyaee Greenhouse City; one hundred residential complexes arranged like beads on a rosary, with shimmering water canals flowing between them like the veins of a living organism. The sunlight passed through the transparent and sturdy roof of the city and shone on the greenhouse plants of the ground floor. The sounds of birds that had been bred in this enclosed space blended with the sound of the water canals, creating a soothing melody that could not be heard in any modern city.

Dr. Amiri, who had spent years researching agriculture and plant sciences, gazed at the city with a wistful look. He remembered how impressed he had been a few months ago when he learned about the inauguration of this city. Now, after several days of living here, he became more convinced every day that this was the city he had always seen in his dreams.

"Do you know why this city has delighted me?" Dr.

Amiri asked without taking his eyes off the city. Dr. Ahmadi, who was sitting beside him sipping tea made from the plants of this very city, turned his head toward him and said, "No, tell me."

Dr. Amiri said: "In the cities where we grew up and worked, everything was based on competition and ownership. Everyone wanted to buy a house, own a car, and have a full bank account. This competition made us forget why we really live. We considered everything personal property, and to preserve this ownership, we were willing to do anything, even if it meant the destruction of nature and our own health."

Dr. Ahmadi nodded in agreement and said: "Yes, I have the same experience. I worked in the field of environment for years and witnessed how modern cities are devouring the earth. Every year, millions of hectares of forests are destroyed so that cities can expand. Billions of tons of concrete and asphalt are poured, preventing water from penetrating the ground and destroying underground water tables. And all of this is because we think we must own something."

Dr. Amiri continued: "But in this city, everything is different. Here, no one owns their house. Everyone has

the right of usufruct, not absolute ownership. When someone does not have a house to speculate on, they no longer worry about preserving its monetary value. They are not worried that if they do not change this house, its value will decrease. They only worry whether this house meets their needs. And this thinking has changed the entire economic and social structure of the city."

Dr. Ahmadi said: "Do you know what is even more interesting to me? This city is inspired by the model of natural colonies. Ants, termites, honeybees; all these creatures, without having personal ownership, have built a complex and efficient society. They share everything and work toward a common goal. None of them think about accumulating wealth, because they know that if the colony is destroyed, everyone will be destroyed."

Dr. Amiri said: "Exactly. In this city, we have learned that humans can live without personal ownership. Not only can they, but it is the best option. Because personal ownership is the root of all our problems. Poverty, war, environmental destruction, inequality; all of these are somehow tied to personal ownership. When someone does not own anything, there is no need for

competition. No need to lie and deceive. No need to step on others to get something."

Dr. Ahmadi stood up and walked to the edge of the rooftop. From there, he could see the water canal flowing like a silver serpent among the complexes. Small autonomous boats moved on rails installed at the bottom of the canal. Passengers sat inside the boats, comfortably enjoying the beautiful greenhouse scenery around them. There was no honking, no smoke, no traffic.

He said: "Do you see how everything is in harmony? These water canals serve multiple purposes: beauty, transportation, and air ventilation. These greenhouses on the ground floor produce food, purify the air, and uplift the human spirit. This transparent ceiling lets in sunlight while protecting against snow, rain, and wind. Everything is multifunctional. Nothing is wasted."

Dr. Amiri stood beside him and said: "And this is exactly what we lost in modern cities. In our ancient cities, bazaars were multifunctional. Mosques, besides worship, were centers of education and social gathering. Bathhouses, besides cleaning, were places for conversation and trade. But in modern cities,

everything became single-purpose. Houses are only for sleeping, offices only for working, stores only for shopping. And this single-purpose approach has separated us from each other and turned loneliness into the biggest problem of modern cities."

Dr. Ahmadi said: "Do you remember what we said on the first day we came to this city? We said this city is like an ocean liner. Everything is integrated and coordinated. No part is independent. If one part breaks down, the entire city is affected. That's why we all must take care of each other. This is exactly what exists on ocean liners. Crew members must cooperate with each other for the ship to reach its destination."

Dr. Amiri said: "And this is exactly what exists in a bee colony. Bees have divided the tasks. Some collect nectar, some take care of the eggs, some keep the hive clean, some protect the hive. None of them think their work is more important than the others. Everyone works toward a common goal: the survival of the colony. And this is what this city has learned from nature."

Dr. Ahmadi turned back and sat on a bench. He said: "Do you know what has impressed me the most? In this

city, no one is idle. Everyone must do four hours of useful work every day. This work can be agriculture, education, medicine, art, or anything that helps the community. But everyone must work. And this work is not for money, but so that everyone has a share in this society."

Dr. Amiri said: "Yes, and this is exactly what we lost in the outside world. In modern cities, millions of people don't work, not because of laziness, but because the system doesn't allow them to work. Either they can't find a job, or their work pays so little that it doesn't sustain their lives, or they've been set aside because of age or health. But in this city, everyone can work. Even the elderly, even people with disabilities, even those whom the outside world didn't value at all."

Dr. Ahmadi said: "And this is what we need. We need everyone to feel that their existence has meaning, that their work is valuable, that the community needs them. This sense of belonging is the most important thing a human being can have. Without this feeling, a person feels lonely and identity-less. And loneliness and identity-loss are the roots of all psychological and social problems."

Dr. Amiri said: "Do you know why I am so interested in this city? Because this city is the city of the future. The city we must build. A city where humans and nature live together, not in war with each other. A city where everyone cooperates, not competes with each other. A city where real justice prevails, not superficial justice. A city where real peace exists, not a peace manufactured with drugs, alcohol, and television."

Dr. Ahmadi said: "And most importantly, this city shows that we can. We can build a city where everything is optimal, where nothing is wasted, where people are happy. We don't have to live the way we used to. We can change. We must change."

Dr. Amiri said: "Yes, and this change starts right here. From our minds. From accepting that the path we've taken so far was not the right path. From accepting that we can live better. From accepting that we are part of nature, not its master. From accepting that we must take care of the earth, not extract from it."

Dr. Ahmadi said: "And this city is an example of what we can build. This city shows that with technology, artificial intelligence, and intelligent design, we can build a city that is good for both humans and the

environment. We can build a city where the air is clean, the water is pure, the food is healthy, and the people are happy. We can build a city where everyone feels a sense of belonging, a sense of security, a sense of meaning."

Dr. Amiri said: "And this is only the beginning. This city can serve as a model for thousands of other cities around the world. We can build this city in the desert, in the forest, in the mountains, by the sea. We can build cities similar to this one with different climatic and cultural conditions. Each city can have its own unique characteristics, but the fundamental principles will be the same: cooperation instead of competition, sharing instead of ownership, nature instead of concrete."

Dr. Ahmadi said: "And most importantly, this city shows that we can learn from past mistakes. We can build cities that do not repeat the same mistakes. Cities without pollution, without traffic, without poverty, without loneliness. Cities where people truly live, not just survive."

Dr. Amiri said: "Do you know what gives me more hope? That this city is truly dynamic. This is not just a theory, not a dream, not a slogan. This is a reality. One million people live in this city and every day they live

better than yesterday. This shows that we can. It shows that change is possible. It shows that a brighter future exists."

Dr. Ahmadi stood up and looked at the city again. He said: "And this future is a future we must build. Each of us must play a role in this building. We may not be able to build a city, but we can spread the ideas. We can talk to others about this city. We can encourage those who are interested. We can raise our children with these ideas. We can learn from this city and make changes in our personal lives."

Chapter Four: Tourist Attractions of the Niyaee Planetary Greenhouse City

The Niyaee Planetary Greenhouse City, as one of the most innovative urban planning projects of the twenty-first century, possesses an unparalleled capacity to attract tourists from around the world. Designed with inspiration from natural colonies such as honeybees, ants, and termites, this city is not only a sustainable human habitat but has also transformed into an exceptional tourist destination that has no equal anywhere on Earth. The tourist attractions of this city stem from a unique combination of natural factors, innovative architecture, advanced technology, and cultural-social experiences that collectively create an unforgettable journey for every visitor.

The first and perhaps most significant factor attracting tourists to the Niyaee City is its unique greenhouse architecture. Built in coastal areas at sea level or below sea level, this city is covered with a transparent and resilient roof that delivers sunlight to the desired and required levels for residents and plants within the city. This massive glass ceiling, constructed from advanced materials resistant to weather conditions, provides a dreamlike view of the sky and clouds for residents and

visitors alike, as if humans are situated in the heart of nature while simultaneously being in a completely safe and protected environment. This visual experience, unattainable in any other city, can alone attract millions of tourists to this city. Visitors can walk beneath the glass roof among green plants and trees while watching the blue sky, all while being protected from wind, rain, and snow. This unique combination conveys a sense of living in nature that has been completely lost in modern cities.

Naturally, one of the most attractive sections of this city for tourists is the magnificent greenhouse of the ground floor, which serves as the beating heart of the city. This greenhouse, covering a vast area, is not only the site for cultivating summer crops needed by residents but also functions as a public green space that brings pleasant air ventilation, environmental beautification, and morale enhancement for citizens. Walking alongside lush green rows of plants, breathing fresh and clean air regulated through intelligent ventilation systems, and enjoying the fragrance of fresh plants and vegetables, is an experience that no park or garden in the world is capable of providing. In this greenhouse, tourists can witness the cultivation and growing of organic products

up close and even participate in the harvesting process. This interactive experience creates a deeper and more meaningful connection between humans and nature that has been completely forgotten in modern urban life.

The water canals designed throughout the city, particularly on the ground floor, are another element that doubles the tourist attraction of this city. These canals, used not only for beautification and air ventilation but also for transporting goods and citizens, have created a dreamlike and serene landscape. The autonomous boats moving on rails installed at the canal floor evoke a scene reminiscent of Venice, with the difference that these boats are completely intelligent, driverless, and produce no pollution. Tourists can ride these boats passing alongside the greenhouse green spaces and enjoy the natural beauties of the city. The gentle sound of water flowing through the canals, along with the mild breeze created by the city's intelligent ventilation system, provides a completely tranquil environment for visitors. This experience, combining natural beauty and advanced technology, conveys a sense of the future while simultaneously evoking a nostalgic feeling of living in nature.

One unique aspect of tourism in the Niyaee City is the opportunity to observe and interact with animals and birds living in the greenhouse space between complexes. Unlike modern cities where wild animals have been completely eliminated, the Niyaee City has provided suitable space for birds and small animals to live alongside humans. The sound of birdsong echoing among plants and bushes displays a vivid and dynamic image of harmony between humans and nature. This experience, unattainable in any other modern city, holds extraordinary appeal especially for children and families. Visitors can closely witness the lives of birds and animals, their feeding, and even their nest-building, while experiencing a sense of closeness to nature. This interaction with urban wildlife is a part of the tourism experience that distinguishes the Niyaee City from any other tourist destination.

The intelligent and small monorails designed in the city for passenger transportation have themselves become one of the tourist attractions. These driverless monorails controlled by intelligent systems move on specific routes and provide a comfortable, safe, and uninterrupted experience for residents and visitors alike. Tourists can ride these monorails passing over

the city and observe a complete view of the greenhouse green spaces, water canals, and organized buildings of the city. This view, combining modern architecture and lush greenery, displays a dreamlike image of the future city found nowhere else in the world. Furthermore, the small and modular design of these monorails is such that if one unit malfunctions, the next unit immediately replaces it and repairs are quickly performed, guaranteeing uninterrupted service for tourists.

The absence of private vehicles and their replacement with clean transportation such as boats, electric scooters, and intelligent cable cars has brought a calm and pollution-free environment to the city. This tranquility, completely rare in modern cities, has itself become one of the main tourism attractions. Visitors who are usually tired of the noisy and stressful life of big cities can experience real tranquility for the first time in their lives in the Niyaee City. The absence of car horns, traffic, smoke, and pollution has created an environment where humans can easily breathe, think, and enjoy the beauties around them. This tranquility, achieved through intelligent city design and the elimination of combustion vehicles, is an experience that no luxury hotel or resort is capable of providing.

The first and second floors of each complex, designed with a height of five meters, accommodate diverse spaces for services, education, healthcare, culture, and entertainment. These floors, aimed at meeting residents' needs in less than five minutes, also hold tremendous appeal for tourists. Visitors can explore advanced educational centers, cultural and artistic spaces, well-equipped medical facilities, and diverse entertainment amenities. Additionally, one of these floors hosts the intelligent production and assembly of lightweight industrial and computer components based on artificial intelligence, which has itself become a scientific-tourist attraction. Technology enthusiasts can closely witness intelligent manufacturing processes and familiarize themselves with robotic systems and artificial intelligence. This blend of tourism with education and technology has transformed the Niyaee City into an ideal destination for families and science and technology enthusiasts.

The integrated management system of the city, inspired by ocean liner management, has itself become an attractive destination for management and organization enthusiasts. Visitors can familiarize themselves with how this massive city is governed and closely observe

how artificial intelligence and advanced algorithms control all aspects of urban life—from transportation to food distribution, from energy management to healthcare delivery. This educational experience, unattainable in any other city, is highly appealing to city managers, management and computer science students, and futurists. They can witness how a city can be efficiently and intelligently managed without the need for large governments and complex bureaucracies.

The absence of private property and the public shareholders system in Niyaee City presents a unique economic model that is particularly attractive to tourists, especially economists and social science experts. Visitors can closely observe how citizens, without private ownership of land and buildings, collectively benefit from urban facilities while simultaneously bearing responsibility for their maintenance and development. This practical experience of life without private ownership offers valuable lessons for addressing housing crises, social inequality, and environmental degradation in modern cities. Many tourists who struggle with housing problems and soaring prices in their own cities can

observe an alternative and operational model in Niyaee City—one that may inspire similar solutions elsewhere in the world.

In summary, the Niyaee Planetary Greenhouse City presents a unique combination of natural beauty, advanced technology, tranquility, and prosperity in a singular tourism package. This city, not merely a habitat but a complete experience of future living, can attract millions of tourists from around the world annually. Visitors who tour this city not only return with unforgettable memories but will also have their perspectives transformed regarding the possibility of living in harmony with nature while leveraging technology for human welfare. Niyaee City demonstrates that a brighter and more sustainable future for humanity is possible—and this hopeful message stands as the most significant tourism attraction of the city.

Chapter Five: Points of Divergence and Convergence Between the Two Niyaee City Models

The Niyaee Planetary City and the Niyaee Planetary Greenhouse City represent two innovative and revolutionary paradigms in futuristic urban planning, designed with inspiration from intelligent natural structures and with the aim of creating a sustainable, healthy, and human-centric environment. Despite their numerous shared philosophical and structural foundations, these two cities exhibit fundamental differences in certain key aspects, and understanding these differences is essential for a comprehensive grasp of each model.

First and foremost, it must be stated that both cities are designed based on the model of natural colonies such as honeybee colonies, ant colonies, and termite colonies. This inspiration from nature is not merely an aesthetic metaphor; rather, it is rooted in engineering and management principles that have been tested through millions of years of evolution in the natural world. In both cities, the structure is founded upon cooperation, self-organization, and collective self-management, with no trace of centralized power hierarchies or private automobiles. Both cities are

designed for a population of one million inhabitants, organized within one hundred separate residential complexes, each accommodating ten thousand residents, and each city spans a radius of fifteen kilometers. These similarities indicate that both models share a common urban planning foundation that aims to combine human scale, five-minute access to services, and environmental preservation.

One of the most significant differences between these two cities lies in the management of green spaces and agricultural and food production. In the Niyaee Planetary City, green spaces, orchards, agricultural lands, and livestock and poultry units are situated on the city's periphery, within a square-shaped, ring-like zone surrounding the residential neighborhoods. This design places agriculture and food production at a reasonable distance from residential areas while still remaining within the urban boundary. In contrast, in the Niyaee Planetary Greenhouse City, all agricultural and production activities are concentrated on the ground floor, within an enormous greenhouse structure that covers the entire city. This divergent approach results in different daily life experiences for the residents. In the Greenhouse City, citizens are in constant direct

contact with living nature and green crops; they can even hear the sounds of birds and domestic animals among the one-hundred-meter spaces between complexes. Meanwhile, in the Niyaee Planetary City, nature and agriculture are located on the city's outskirts, requiring a short journey to access them.

Regarding geographical positioning and subsurface structure, these two cities exhibit notable differences. The Niyaee Planetary Greenhouse City is constructed in coastal regions, at sea level or below sea level, and consequently, no excavation is undertaken in the ground. This constraint arises from two factors: first, the protection and preservation of soil as one of the most valuable natural resources that must not be subjected to destructive alterations, and second, the prevention of seawater infiltration into underground layers. Accordingly, the Greenhouse City has no basement levels, and all activities are conducted on above-ground floors. Conversely, the Niyaee Planetary City does not face this limitation and can be constructed in diverse regions—including plains, foothills, or areas elevated above sea level—thus naturally allowing for the use of subterranean levels for parking, storage, and infrastructure. Nonetheless, both

cities emphasize the prevention of excessive land destruction and the preservation of groundwater aquifers.

In the Niyaee Greenhouse City, due to its location at sea level or below sea level, asphalt and concrete are not used for streets and city beds. This decision was made with the aim of preserving the soil's permeability and enabling the replenishment of underground water aquifers through any available moisture. Instead, permeable materials and natural soil are used for flooring so that the water cycle in nature is preserved. Of course, this approach is not very different from the Niyaee Planetary City, where, although there is great emphasis on environmental preservation, the urban structure can include streets and public spaces with various useful materials, which are always designed with environmental principles and sustainability in mind.

One of the unique features of the Niyaee Greenhouse City is its complete isolation system. This city is designed in such a way that no snow, rain, or direct wind penetrates the city. The glass and transparent roof of the city provides sunlight as needed by the residents and plants inside the greenhouse, while preventing the

entry of adverse weather conditions. This structure ensures that the city has pleasant and controlled weather throughout the year, and intelligent ventilation systems maintain optimal air circulation throughout the city. In the Niyaee Planetary City, although intelligent climate management systems are used, the city is not completely isolated and still interacts with the surrounding weather conditions, although the negative effects of unfavorable conditions are reduced through intelligent design and plant covers.

In both cities, lightweight and durable prefabricated materials are used, and there are no traditional heavy concrete structures or massive steel columns. This approach allows the city to be built quickly and eliminates the need to transport millions of tons of materials. In the Greenhouse City, prefabricated components are mounted on piles that are bolted to the ground, eliminating the need for traditional concrete foundations. This construction method is largely similar in the Niyaee Planetary City, as both cities are based on the principles of lightweight, rapid, and sustainable construction.

In the Niyaee Greenhouse City, the ground floor is designed as a large greenhouse with very precise,

specialized, and intelligent ventilation. In addition to growing the vegetables needed by the people, this greenhouse provides a designated space for citizens to move and transport goods through special boats. The boats move on rails installed at the bottom of the water canal, and the water current is not the means of their movement. These water canals, in addition to their transportation role, contribute to beautifying the environment, ventilating the air, and creating recreational and tourism spaces. In the Niyaee Planetary City, the transportation system is designed somewhat differently based on cable car, monorail, boats, electric scooters, and drones. This difference in transportation approach has different results in terms of residents' experience: in the Greenhouse City, citizens can move in a green space with the sound of water, while in the Planetary City, air and light rail transportation is more prominent.

In both cities, self-driving monorails are used for passenger transportation, but the approach is different. In the Greenhouse City, monorails are designed in large numbers and small dimensions so that if one fails, the next monorail quickly replaces it and the repair of the defective vehicle is done rapidly. This approach

minimizes transportation downtime. In the Niyaee Planetary City, similar systems based on intelligence and self-driving capability are also used.

In terms of number of floors, both cities share a similar approach, but with certain differences. In the Greenhouse City, each complex consists of ten floors: the ground floor is designated as a greenhouse, the first and second floors each have a height of five meters and are allocated for services, education, healthcare, culture, and light industrial production, and the remaining seven floors, each with a height of two meters and eighty centimeters, are designated for residential purposes. This structure ensures that residents' needs are met within a five-minute walking distance from their homes. The Niyaee Planetary City also has a similar structure with an emphasis on rapid access to services, but the exact details of the floors may differ.

In both cities, the management system is designed based on the model of ocean liners—a city that is administered in an integrated and coordinated manner, with all components interacting with one another. Neither city has personal ownership; land, buildings, and facilities are collectively owned by the residents

through public shares. This approach eliminates capital accumulation, hoarding, and price inflation driven by the pursuit of greater ownership, thereby guaranteeing social justice. In both cities, artificial intelligence and smart algorithms play a key role in management, resource distribution, and activity coordination.

In summary, the Niyaee Planetary City and the Niyaee Greenhouse City are two complementary approaches to future urban planning. The Planetary City emphasizes interaction with the external nature and utilization of surrounding natural resources, while the Greenhouse City possesses both an internal, fully controlled ecosystem and external nature on the city's periphery. Both models represent significant strides toward realizing a sustainable, healthy, and humane city where humans and nature coexist in peace.

Chapter Six: Attracting Capital Based on Values and Intangible Assets

In the modern world of economics, a phenomenon has emerged that has captured the attention of numerous analysts and economists: the staggering disparity between the value of tangible assets and the value of branding in organizations and sports teams. When we examine renowned football teams such as Real Madrid, Barcelona, and Manchester United, or American basketball teams like the Los Angeles Lakers, we observe that the brand value of these teams often exceeds several times the value of their physical assets. The playing field where they compete, the headquarters building, equipment, and even the properties owned by the club constitute only a small fraction of the true value. What has transformed these teams into billion-dollar enterprises is a collection of intangible values constructed and refined over decades.

The question of why a sports team without owning land or luxurious properties in strategic locations around the world can possess far greater value than a team that possesses all these facilities has a profound and multidimensional answer—one that can serve as a powerful model for novel urban development projects

such as the Niyaee Planetary Greenhouse City. The answer to this enigma lies in understanding the nature of brand and the distinction between it and physical assets. A sports team's brand is composed of numerous elements, the most significant of which include long-term strategic plans, experienced and specialized management and technical personnel, transparent regulations and organizational structures, an ethical and disciplined organizational culture, teamwork and collective effort, and ultimately, inspiring histories and narratives. These elements, collectively, form what economists refer to as intangible capital or intangible assets. A team that has operated with precise planning and intelligent strategies over the years, maintains an orderly and disciplined staff, whose players conduct themselves with ethics and discipline, and whose organizational culture is founded upon respect, honesty, and teamwork, gradually attracts loyal fans who do not merely support the team for game results, but become devoted because of the identity and values that the team represents. These fans, regardless of momentary outcomes, accompany the team through all conditions, and this loyalty represents a capital that cannot be purchased with money.

The difference between successful and unsuccessful teams lies in the fact that successful teams invest in building these intangible values, while other teams focus solely on purchasing expensive players or leasing luxurious lands. When a sports team possesses an experienced technical staff that has operated at the highest levels for years and has transferred its experience and knowledge to subsequent generations, this experience becomes a valuable heritage from which every new player joining the team benefits. Furthermore, when the internal regulations and laws of the team are transparent and fair, and all members—from technical staff to young players—are subject to a logical system, mutual trust and respect develop, resulting in better performance and more desirable outcomes. This orderly system is precisely what attracts investors and financial sponsors, not because of the team's properties or equipment, but because of the assurance that their capital will be managed within a structured and disciplined environment.

This economic model, in which investors allocate capital based on intangible and non-physical values, carries profound implications for large-scale urban development projects. In the Niyaee Planetary

Greenhouse City project, the same paradigm can be leveraged to transform the city—not based on land and buildings, but on the fundamental values that this city represents—into a brand. These values encompass: the philosophy of non-private ownership and public shareholding; a smart, algorithmic management system; a culture of cooperation and teamwork inspired by natural colonies; a commitment to environmental and soil preservation; innovation in sustainable architecture; and social justice in resource distribution. Each of these values, individually, can attract investors seeking projects with foresight and social responsibility. However, their combination creates a multiplied force that no other urban project can compete with.

Today's intelligent investors are no longer solely seeking short-term financial returns. Many of them are looking for projects that are meaningful, that generate positive impacts on society and the environment, and that are simultaneously profitable. The Niyaee City, with this approach, can attract this category of investors. By purchasing shares, they are essentially investing in an idea and an ideal, not merely in a piece of property or land. This type of investment is more

sustainable and resilient against market fluctuations, as its value is built upon trust in a system and culture, rather than being tied to real estate price volatility.

The next step in this trajectory is the conversion of these intangible values into a cryptocurrency or digital token representing shares and participation in the Niyaee City project. In this model, purchasing shares in the Niyaee City equates to acquiring digital tokens, each representing a portion of ownership and the right to utilize the city's facilities. These tokens are designed based on the city's intangible values, and their price is determined not by pure supply and demand, but by trust in the system and the project's growth. In the first phase, investors purchase these tokens solely based on these values, without any physical assets of the city having been constructed yet. This phase resembles investing in startups, where investors commit their capital based solely on an idea and the founding team.

The advantage of this approach lies in the fact that the first phase attracts individuals who genuinely believe in the city's values and are willing to accept the risk of investing in an innovative project. These individuals not only contribute financial capital but also stake their social capital and credibility on the project, acting as

brand ambassadors. They narrate the story of the Niyaee City to others, encourage others to participate, and essentially build a network of loyal supporters who promote the city's values. This network, in subsequent phases—when the city is constructed and its tangible assets take shape—serves as a solid foundation for attracting further investment.

In the second phase, when the Niyaee City is physically built and its residential complexes, greenhouses, water canals, monorails, and all infrastructure become operational, the value of tokens is further reinforced by these tangible assets. This is where the return on investment doubles, as early investors—who invested solely based on trust in values—are now owners of both the intangible brand value and a share of the city's physical assets. This two-phase model guarantees that the city is built from the very beginning on a solid foundation of trust and conviction, while simultaneously benefiting from wealth and real assets in later stages.

The difference between this model and traditional models lies in the fact that in conventional methods, land is first purchased, buildings are constructed, and then sold. In this process, buyers decide solely based

on the property's value and physical amenities, having no emotional or identity-based connection to the project. However, in the Niyaee City model, investors become partners in the process of building an ideal from the very beginning, and this partnership creates a sense of belonging and responsibility that does not exist in traditional models. They are not merely owners of a part of the city, but owners of an idea and an ideal.

One of the most significant advantages of this model is its long-term sustainability and durability. Traditional cities face numerous challenges such as rising land prices, environmental degradation, social inequality, and dependence on fossil fuels. However, the Niyaee City, by relying on its intangible values, is immune to these problems. The smart, algorithmic management system guarantees that decisions are made based on data and logic, not on personal interests or political pressures. The philosophy of non-private ownership prevents wealth accumulation and the creation of social classes. The commitment to soil and environmental preservation guarantees that the city remains habitable for future generations. And the culture of teamwork, inspired by natural colonies, guarantees that all citizens work toward a shared goal.

These values are the very elements that transform successful sports teams into brands, and they can transform the Niyaee City into a global brand—one that is not only physically attractive but also spiritually and identifiably valuable. Investors who believe in these values, even if they never reside in the city, take pride in being part of this project, and this pride is a value that cannot be purchased with money.

Final Interpretation

The comprehensive study of the Niyaee Planetary Greenhouse City demonstrates that humanity stands at the threshold of a fundamental transformation in its way of life, and this city represents a practical example of a future in which humans and nature coexist not in opposition, but in peaceful coexistence with one another. What has been designed and articulated in this book as the Niyaee Greenhouse City is not merely an architectural or urban planning scheme, but rather a comprehensive manifesto regarding humanity's attitude toward the Earth, resources, neighbors, and ultimately toward humanity itself. This city has been constructed inspired by natural colonies of honeybees, ants, and termites—creatures that have lived in complete harmony with the environment for billions of years without personal ownership of the land, and while enjoying God's blessings, they continuously produce, reproduce, and serve the colony. This natural model demonstrates that ideal utilization of God-given resources is possible with the least possible environmental destruction, while simultaneously building a dynamic, productive, and just society.

One of the most significant lessons that can be drawn

from the study of this city is the redefinition of the concept of ownership in the present era. In the current system of modern cities, full ownership (six-dang) is recognized as the absolute right of individuals over property and assets, and this thinking has resulted in enormous wealth being concentrated in the hands of a small minority, while the majority of people are deprived of access to life's minimum necessities. In the Niyaee City, however, land, buildings, and all facilities are provided to residents in the form of public shares, and no individual has the right to hoard, stockpile, or engage in price manipulation with the aim of acquiring greater ownership. This system, rooted in Islamic philosophy, which regards humans as God's viceroy on Earth rather than its absolute owner, guarantees that resources are distributed equitably among all and that no one in this city remains deprived of the vulnerable segments of society. Smart blockchain contracts also guarantee the enforcement of this justice without the need for courts or officers.

The Niyaee Greenhouse City, with its unique design in coastal areas at sea level or below sea level, has demonstrated that a modern and advanced city can be built without any excavation in the ground and without

harming underground water reservoirs. This approach, which emphasizes the protection of soil and the restoration of its capabilities, stands in stark contrast to current urban development, which imposes millions of tons of concrete and asphalt upon the Earth's surface and disrupts the natural water cycle by blocking the pores of the soil. In the Niyaee City, not even one square meter of asphalt or concrete is used for the city's base and passages, and all moisture infiltrates through the soil into underground reservoirs so that the vital water cycle is preserved. This courageous decision demonstrates that urban development does not necessarily mean environmental destruction, and that a city can be built that coexists with the Earth rather than in opposition to it.

The intelligent classification of the ten-story complexes in this city is also noteworthy. With the complete elimination of basement floors due to being at sea level and the protection of soil, the designers have been able to transform the ground floor into a massive greenhouse with green spaces, water canals, and precise ventilation, which, in addition to supplying part of the citizens' food needs through the cultivation of summer crops, greatly contributes to beautifying the

environment and strengthening the psychological and mental well-being of the residents.

The first and second floors, with a height of five meters each, are dedicated to providing services in educational, healthcare, cultural, and production domains. The objective is for every citizen to access all their essential needs within less than five minutes. This design is inspired by the integrated management and order found in ocean liners, which fulfill all human needs in the most efficient manner within a confined space.

The transportation system of this city represents a revolution in human thought. By completely eliminating combustion vehicles and replacing them with autonomous boats on rails inside water channels, small smart monorails, electric scooters, and cable cars, the city has been entirely freed from noise and air pollution. The boats, which move on rails embedded within water channels, not only transport goods and passengers but also contribute to creating beautiful landscapes for tourists while providing natural ventilation for the city. Small monorails are designed in large quantities so that if one malfunctions, the next one immediately enters service, ensuring uninterrupted

transportation. This approach, inspired by distributed systems in nature, guarantees that no disruption occurs in the city's flow of life.

One of the most beautiful aspects of this city is its complete isolation from unfavorable natural elements. The city is designed so that no snow, rain, or direct wind penetrates its interior. However, its transparent and highly resistant roof provides sunlight to the extent necessary for the residents. Smart ventilation systems in both hot and cold seasons circulate pleasant and comfortable air throughout the city, ensuring that citizens live in complete comfort at all times of the year. This design also allows for the presence of birds and animals appropriate to the greenhouse environment, eliminating the dull and lifeless appearance of modern cities and allowing residents to enjoy the beauty of living nature at every moment.

The construction speed of this city is also remarkable. Unlike current cities that take years to build and require the transportation of millions of tons of materials, in this city all components are prepared in advance as lightweight prefabricated units and quickly installed on pilings screwed into the ground. This method not only drastically reduces construction time but also prevents

environmental damage caused by the extraction and transportation of heavy materials. The Niyaee City demonstrates that it is possible, with innovative thinking and advanced technologies, to build cities that are both comfortable for humans and bearable for nature.

The tourist attraction of this city is also significant. The greenhouse space with water channels, birds, animals, and pleasant ventilation creates such a relaxing environment that citizens no longer need to travel long distances to enjoy nature and waste their valuable time in traffic. This city can attract millions of tourists from around the world annually and generate very high income for itself and its residents. Tourism in this city is not to escape urban life, but to experience life in nature that has been integrated into the heart of the city.

Ultimately, the Niyaee Planetary Greenhouse City serves as a model for future generations of humanity, demonstrating that it is possible, by drawing inspiration from nature and utilizing artificial intelligence and modern technologies, to build a civilization in which humans live in tranquility, justice, and harmony with the environment without absolute ownership of land and resources. This city is a dream that can become

reality if humans accept that they have not inherited the Earth from past generations, but are trustees who must pass it on to future generations. This is the message that Niyaee City holds for all of humanity: The future belongs to those who coexist with nature, not those who dominate it.
